ABSTRACT

The female of _Saltonia incerta_ (Banks) is redescribed, the presence of large tracheal trunks extending into the thorax is recorded, the epigynum is illustrated and _S. imperialis_ Chamberlin and Ivie is placed as a junior synonym. The type locality, now under water, and other collecting sites of this species are discussed. The systematic position of the spider is uncertain because of the agelenid-like external characters and the dictynid-like palpi and tracheal trunks.

INTRODUCTION

_Saltonia incerta_ (Banks) is a rare spider known from an island in the northern part of the Gulf of California and from the shores of the Salton Sea in Southern California. Recently the type specimen, a mature female, was made available by Dr. Herbert Levi of the Museum of Comparative Zoology. We are taking this opportunity to illustrate the epigynum of this species and to review its history.

_Saltonia incerta_ (Banks)
Fig. 1

_Cybaeodes (?) incerta_ Banks, 1898:185.
_Saltonia imperialis_ Chamberlin and Ivie, 1942:23, Figs. 24-25. NEW SYNONYMY.
_Saltonia incerta_ (Banks), Roth and Brame, 1972:34, Fig. 46.

The above synonymy was noted by W. Ivie (personal communication) a few years before his untimely death but was not published. The new combination was used inadvertently by Roth and Brame (1972:34) without explanation nor synonymic data.

The female is similar to the male in size and general appearance but differs slightly in the leg spination: tibia I, 1r-2-0; metatarsus I, 2(or 1p)-2-1 median. The slightly sclerotized epigynum has lateral openings under heavily sclerotized ridges (Fig. 1).

The internal genitalia were not examined but appear to consist of an atrium, a pair of globular spermathecae with simple connecting canals extending to the epigastric furrow.
Fig. 1.—Epigynum of *Saltonia incerta* Banks (type specimen).

A male in The American Museum of Natural History shows two large tracheae entering the thorax.

**Type data**—Adult female and immature (thorax and legs only) from Salton, California (27 March 1897, H. G. Hubbard), in the Museum of Comparative Zoology, Cambridge, Massachusetts, collected from debris on salt crust.

Two of the three collecting sites can still be located. Unfortunately, Fish Springs is now partially developed into a mineral bath at the Rancho Marina Campground at Desert Shores on the Salton Sea. Salton, California, on the northeastern edge of the Salton Sea, was a railroad station for a salt mining company which worked a nearby salt deposit. This deposit is now underwater but was in the area between the Salton and the Mecca beaches of the present Salton Sea State Park. In 1891 there was a salt marsh west of the railroad at Salton which may be the type locality.

The third locality is questionable as there are three "Pelican Islands" in the Gulf of California (Sea of Cortez), one now nonexistent and the other two somewhat inaccess-ible. One is known locally as Isla El Alcatraz (Spanish for "The Pelican") and is so recorded on at least one Mexican map (Map 1) but is commonly known by American fishermen as Pelican Island, or Isla Pelicano(s) (Maps 2-4). Elsewhere it is listed as Isla Tassne (Map 5). It is a high rocky mountain with some low sandy land covered with desert brush, located at the edge of Kino Bay at latitude 28°49', longitude 111°58'. It has none of the salt marshes one finds around the type locality at the Salton Sea.

The oldest maps (Maps 6-7) place Pelican Island near the junction of the Colorado and Hardy Rivers about 10-12 miles upstream from the Montegue and Gore Islands at the mouth of the Colorado River. The diversion and later damming of this river and the subsequent decrease in water flow caused the island to become permanently attached to the river bank and it was essentially lost. These early maps showed two separate islands whereas more recent maps show the islands joined but partially divided at the southern end with a third unnamed island eastward (Map 8). On the latest maps (Maps 9-10) it is called Pelican Island. This island, which is more likely to be the collecting site of *S. incerta*, lies at the mouth of the Colorado River at latitude 31°45', longitude 114°38'.

The three collections, all containing adult specimens, were made in the months of March and April near salt springs, salt water or salt marshes. Repeated trips to similar
areas including Fish Spring and other springs in the Salton Sea region, Pelican Island at Kino Bay, and along the shores of the Gulf of California have failed to produce additional specimens. Perhaps *Saltonia* has a specialized habitat that has not been exploited by collectors. The similarity of its colulus to two genera of intertidal zone spiders, *Corteza* Roth and Brown and *Desis* Walckenaer suggests that *S. incerta* may be found in a similar marine habitat. *Corteza interaesta* is found at night on rocks and reefs at the upper barnacle zone in the Gulf of California. *Desis* is a widespread genus the species of which are found in rock crevices and worm tubes in the intertidal zone of the Southern Pacific and Indian Oceans from the Galapagos Islands to Eastern Africa.

The systematic position of *Saltonia incerta* remains a puzzle. Banks (1898:185) originally placed it questionably in the genus *Cybaeodes*, commenting, "am uncertain of its position, but I think it very near *Cybaeodes*." Why he placed it in this genus is puzzling since *Cybaeodes* is characterized by its contiguous spinnerets. At that time this genus was placed in the Drassidae by Simon (1893:390) and later Petrunkevitch (1911:532) placed *Cybaeodes incerta* in the Agelenidae. Both Roewer (1954:581) and Bonnet (1956:1297), following Petrunkevitch (1928:175), listed the genus *Cybaeodes*, including *incerta*, in Liocraninae, a subfamily of the Clubionidae. Lehtinen (1967:355) originally placed *Saltonia* in the family Dicytidae, and the subfamily Cybaeinae, but added a footnote on the same page transferring it to Tricholathysinae in the same family without providing evidence for either change.

Except for the widely spaced spinnerets and broad colulus, *Saltonia* has all the external characteristics of the family Agelenidae and will key out readily to this family in Petrunkevitch’s (1939:141-148) key to the spider families. The two large tracheal trunks which extend into the thorax are not, however, typical of any of the Agelenidae but are of the Dicytidae.

Recent extensive reclassification of the cribellate spiders and related ecribellate families by Lehtinen (1967), Forster (1970) and Forster and Wilton (1973) leaves one with the alternatives of utilizing a phylogenetic classification without being able to place specimens in their proper family or using an artificial classification and making it possible to place specimens where they might be found by other workers. With spider classification in such a state of flux, it appears to us to be desirable to take a conservative stand and use the family Agelenidae for *Saltonia* for the present, until some of the problems are settled.
